Computational complexity

- ▶ Focuses on classifying computational problems according to their **inherent difficulty**.
- ▶ A problem is regarded as inherently difficult if solving the problem requires a **large amount of resources**, independent of the used algorithm.
- ▶ Considers **mathematical models of computation** and the **amount of resources** needed to solve them, such as time and storage.

- ▶ **Analysis of algorithms:** To determine the amount of resources (such as time and storage) necessary to execute them.
- ▶ **Computability theory:** For which decision problems do algorithms exist.
- ▶ **Computational complexity theory:** For which decision problems do efficient algorithms exist.

This raises the questions:

- ▶ What ‘resources’ do we wish to be employed ‘efficiently’
- ▶ What do we mean by ‘efficient’?

Computational problems

- ▶ **Multiplication:** Given two integer numbers a and b , compute their product $a \cdot b$.
- ▶ **Dinner party problem:** Given a list of acquaintances and a list of containing all pairs of individuals who are not on speaking terms with each other, find the largest set of acquaintances you can invite to a dinner party such that you do not invite any two who are not on speaking terms.

Efficiency of multiplication

- ▶ **Repeated addition:** add a to itself $b - 1$ times.
- ▶ **Grade-school algorithm:**

$$\begin{array}{r} 12 \\ \times 23 \\ \hline 36 \\ 24 \\ \hline 276 \end{array}$$

Hence, for multiplying two n -digit numbers:

- ▶ The repeated addition uses $n \cdot 10^{n-1}$ additions.
- ▶ The grade-school algorithm uses $2n^2$ additions.
- ▶ The fastest known algorithm the Fast Fourier Transform uses $(c \cdot n \cdot \ln n \cdot \ln \ln n)$ operations.

Efficiency of solving the dinner party problem

- ▶ **Obvious inefficient algorithm:** Try all possible subsets from the largest to the smallest, and stop after a subset that does not include any pair who do not get along.
- ▶ Running time for n people = the number of subsets = 2^n .
- ▶ To organize a 70-person party, supercomputers would spend thousands of years .
- ▶ **Surprisingly:** We still do not know significantly better algorithms!

Representing problem instances

- ▶ When considering computational problems, a problem instance is a **string** over an **alphabet**.
- ▶ Integers can be represented in binary notation, graphs can be encoded via their adjacency matrices.
- ▶ The independent of the choice of encoding can be achieved by ensuring that **different representations** can be **transformed into each other efficiently**.

Upper and lower bounds on the complexity of problems

- ▶ Proving upper and lower bounds on the **minimum amount of time** required by the most efficient algorithm solving the problem.
- ▶ The running time of a particular algorithm is **measured** as a function of the length $|x|$ of the input x .

Interesting questions about computational efficiency

- ▶ Do some tasks inherently require **exhaustive search**? (P vs NP)
- ▶ Can algorithms use **randomness** to speed up computation?
- ▶ Can problems be solved quicker if only **approximate solutions** are required?
- ▶ Can we use computationally hard problems, to construct, for example, **cryptographic protocols** that are unbreakable?
- ▶ Can we use **quantum mechanical properties** to build faster computers?
- ▶ Can we generate **mathematical proofs** automatically?
